ABSTRACT

Electrical discharge machining (EDM) is one of the important non-traditional machining processes and it is widely accepted as a standard machining process in the manufacture of forming tools to produce moulds and dies. Since its introduction to manufacturing industry in the late 1940s, EDM became a well-known machining method. The method is based on removing material from a work piece by means of a series of repeated electrical discharges, produced by electric pulse generators at short intervals, between an electrode (tool) and a part being machined in the dielectric fluid medium. In the present study, the performance parameters of EDM process are to be evaluated to achieve the feasibility in machining of H13 tool steel which has wide application in the Hot punches and dies for blanking, forging, swaging and bending, Nozzles for aluminium, tin, and lead die casting, Hot extrusion dies for aluminium, cores ejector pins, inserts, Hot shear blades. Here the machining is done by EDM using three different electrodes like copper, brass, and bronze and investigates which type of electrode give a better result for increasing MRR, and decrease SR.

The experiments planned, conducted and analyzed using Response surface methodology and it is found that the MRR and SR are mainly influenced by which EDM machining parameter.

Keyword: MRR, SR, EDM, RSM etc.

1. INTRODUCTION

Electrical Discharge Machining, commonly known as EDM is a non-conventional machining method used to remove material from a number of repetitive electrical discharges of small duration and high current density between the work piece and the tool. EDM is an important and cost-effective method of machining extremely tough and brittle electrically conductive materials. In EDM, since there is no direct contact between the work piece and the electrode, hence there are no mechanical forces existing between them. Any type of conductive material can be machined using EDM irrespective of the hardness or toughness of the material. EDM has been substituting traditional machining operations.

Now today EDM is a popular machining operation in several manufacturing productions all over the world’s countries. Most of the traditional machining process such as drilling, grinding, and milling, etc. are failed to machine geometrically complex or difficult shape and size. Those materials are easily machined by EDM non-traditional machining process which leads to broadly utilized as die in addition to mould assembly industries, making aeronautical parts and nuclear instruments at the minimum cost. Electric Discharge Machining has also established its presence touched on the different subject areas such as make use of sporting things, medicinal and clinical instruments as well as motorized research and development regions.
2. PRINCIPLE OF EDM

In this process, the material is removed from the work piece due to erosion caused by rapidly recurring electrical spark discharge between the work piece and the tool electrode. There is a small gap between the tool and the work piece. The work piece and tool both are submerged in dielectric fluid, commonly used are EDM oil deionized water, and kerosene.

![Fig.1.1 Principle of EDM](image)

3. CLASSIFICATION OF EDM

Basically, there are two types of EDM: Die-sinking EDM and Wire-cut EDM

**Die-Sinking EDM:** Die-sinking EDM, also known as Volume EDM or cavity type EDM consists of an electrode and a work piece which is submerged in an insulating fluid such as oil or other dielectric fluids.

**Wire-cut EDM:** Wire-cut EDM, also known as Spark EDM is mostly used when low residual stresses are required, as it does not needs high cutting forces for removal of material.

![Fig.1.2.die sinking EDM & wire cut EDM](image)

4. IMPORTANT PARAMETER OF EDM

- **Spark time or (pulse on time \( T_{on} \)):** It is the duration of time expressed in micro seconds in which the peak current is ready to flow in every cycle. This is the time in which energy removes the metallic particles from the work piece.
- **-time (pause time or \( T_{off} \)):** It is the duration of time (μs) between the sparks (that is to say, on-time). This time allows the molten material to solidify and to be washed out of the arc gap. This parameter is to affect the speed and the stability of the cut. Thus, if the off-time is too short, it will cause sparks to be unstable.
- **Arc gap (or gap):** It is the distance between the electrode and the part during the process of EDM. It may be called as a spark gap.
- **Duty cycle:** It is a percentage of the on-time relative to the total cycle time. This parameter is calculated by dividing the on-time by the total cycle time (on-time plus off-time). The result is multiplied by 100 for the percentage of efficiency or the so-called duty cycle.
- **Intensity (I):** It points out the different levels of power that can be Supplied by the generator of the EDM machine.\( I \) represents The mean value of the discharge current intensity.
- **Discharge current (Ip):** Current is measured in ampere (A) allow to per cycle. The discharge current is responsible directly for material removal. It contains energy for melting and evaporation.
- **Voltage (v):** It is a potential that can be measured by volt it is also affected the material removal rate and allowed to per cycle.
5. CHARACTERISTIC OF EDM

6. LITERATURE REVIEW

In this chapter, some selected research papers have been discussed related to Electrical Discharge Machining. The studies carried out in these papers are mainly concerned with the EDM parameters such as current, voltage, pulse on time, duty cycle, etc. and selected specific electrode for machining specific material and also shows that how these affect the machining characteristics like MRR, SR, TWR etc.

10 Examination of machining parameters on surface roughness in EDM of tool steel. M. Kiyak, O. Cakir 2007 (Journal of materials processing technology) (JMPT). 40CrMnNiMo8 64 tool steel with the cylindrically shaped copper electrode. to study of the influences of EDM parameters on surface roughness for machining of40CrMnNiMo864 tool steel (AISI P20) which is widely used in the production of plastic mould and die. The selected EDM parameters were pulsed current, pulse time and pulse pause time. It was observed that surface roughness of work piece and electrode were influenced by pulse current and pulse on time, higher values of these parameters increased surface roughness. Lower current, lower pulse time and relatively higher pulse pause time produced a better surface finish.

11 Parametric Optimization for MRR on H-13 Die Tool Steel on EDM using Taguchi Techniques. Pardeep Narwal, Jai Singh 2017 International Journal of Engineering and Management Research (IJEMR). H 13 tool steel with copper electrode purpose of this paper to The works on h13 tool steel shows the effect of various process parameters like peak current, Pulse on Time, and Feed rate on Material Removal Rate using EDM Drilling. For the response variables, Taguchi technique is used. According to this research paper, we give the results that following parameters such as current [55.78%], Pulse on time[26.40%] and feed rate [7.75%] which are influencing metal removing rate(MRR). MRR is influenced by current, Pulse on time and feed rate respectively. We know that MRR which is a volumetric loss of H-13 die tool steel is highly influenced by the current.

12 Analysis of EDM Process Parameters Using Response Surface Methodology And Grey Relational Analysis. Vishwajeet Kumar, Prof. Rakesh. 2016 International journal of scientific research and education (IJSRE) EN-31 tool steel with copper electrode In this study, pulse on time, duty cycle, discharge current and gap voltage are chosen as machining parameters for performance characteristics material removal rate (MRR) and surface roughness (SR). The experiments were designed and performed on the basis of response surface methodology (RSM). The experiments have been performed by using RSM. The discharge current is the most significant factor for material removal rate as well as surface roughness. The increase in discharge current produces a stronger spark. It generates higher temperature, which causes more material to melt and erode from the work piece. Therefore, MRR and SR increase with an increase in discharge current. The material removal rate decreases with rising in gap voltage. It has also a significant effect on of gap voltage is lesser than discharge current.

7. RESEARCH GAP

- According to the specific application of H13 tool steel such as ejector pin, inserts, cores, forging die extrusion die and hot shear blade manufacture so we have to select H13 tool steel as work piece material.
- H13 is hardening tool steel which has excellent high tensile properties, high wear resistance, and adequate toughness and resists tempering at high operating temperature.
- From the above research paper, it is observed that work has been done on H13 tool steel with only copper and graphite electrode
- So the objective of the present work is to investigate the effect of three different electrode like copper, brass, and bronze on H13 tool steel while machining will do by EDM and also show the influence of different electrode on process parameter and find which response parameter is most affected by in out of this three input parameter.
- The input parameter has been selected pulse on time, pulse off time and discharge current.
8. METHODOLOGY

The response surface method is the best method to optimizing output variable. A central composite design is the most commonly used response surface designed experiment. Central composite designs are a factorial or fractional factorial design with center points, augmented with a group of axial points (also called star points) that let you estimate curvature. You can use a central composite design to:

- Efficiently estimate first- and second-order terms.
- Model a response variable with curvature by adding a centre and axial points to a previously-done factorial design.
- Central composite designs are especially useful in sequential experiments because you can often build on previous factorial experiments by adding axial and center points.
- The **central composite design** and three-level full factorial design created significantly better models comparing to the other methods.

By using CCD design we have to generate a graphical analysis of output parameter like MRR, SR, and EWR according to their level, by using MINITAB software. The response regression analysis will be done by central composite design.

9. EXPERIMENTAL SETUP

- In this research study, EDM characteristic such as MRR, EWR, and SR is considered as the output responses for EDM Machining. Experimental set up is as under

![Fig 1.3 experimental setup](image)

- During the EDM process, both the work piece and tool electrode is eroded. MRR is calculated as the work piece weight loss over the machining time. Simultaneously EWR is expressed as the ratio of tool weight loss to the machining time and wear ratio is expressed as the ratio of decrease in length of the electrode to the length of work piece machined.

- **GRAPHICAL ANALYSIS FOR COPPER ELECTRODE: MRR VERSUS CURRENT, PULSE ON TIME, PULSE OFF TIME**
From the analysis of variance table 5.2.2, it is seen that current, pulse on time and pulse off time having value is less than α-level 0.05 which is shows that current, pulse on time and pulse off time is a most significant factor for material removal rate.

10. CONCLUSION

By analyzing the results of the experiment on H13 die tool steel with copper, brass and bronze electrode materials, the following conclusions are arrival at.

- Higher material removal rate obtained using copper electrode as compared to brass and bronze electrode.
- Copper electrode offers lower electrode wear rate compared to brass and bronze electrode.
- Surface roughness is better for the brass electrode as compared to copper and bronze electrode.
- Current is most significant process parameter for material removal rate and electrode wear rate for copper electrode drawn by Response surface analysis.
- Current and pulse on time are most significant process parameter for electrode wear rate and Surface Roughness for brass drawn by Response surface analysis.
