ABSTRACT

Andrographis paniculata, commonly known as Kalmegh, is used both in Ayurvedic and Unani system of medicines because of its immunological, antibacterial and hepatoprotective properties. It is an annual herb with a high-value compound used in the treatment of various diseases. A field experiment was conducted at the research farm of RAK College of Agriculture, Sehore (Madhya Pradesh) during Kharif 2015-16 and 2016-17. Investigations were undertaken to aim to increase the growth and yield parameters of Kalmegh. Using different Plant Growth Hormones Cycocel (100, 150 and 200ppm), GA3 (100, 150 and 200ppm) and NAA (100 and 150ppm) and water spray as control to study the effect of plant growth hormones on Growth viz plant height (cm), leaf area (cm²), chlorophyll content (SPAD), photosynthesis rate (μmol CO₂ m⁻² s⁻¹) at 90 DAS and yield viz test weight (g), seed yield (kg ha⁻¹), and leaf area.

Keywords — Cycocel, GA3, NAA spray, PPM, Photosynthesis rate, Chlorophyll content

1. INTRODUCTION

Kalmegh (Andrographis paniculata Burn F. Ex) important medicinal plant belonging to the family Acanthaceae. Which is indigenous to India and has been used in Indian systems of medicines since time immemorial. The plant is also known as Rice bitters in West Indies and the king of bitters or Chiretta in England. It is an erect or recumbent, annual herbaceous plant. The branches are quadrangular, leaves simple petiolate, lanceolate with acute base and apex. Flowers are small, solitary and panicles with externally hairy rose or purple colored corolla, calyx-lobes glandular, pubescent, anther bearded at the base, fruits 20 mm long linear-oblong capsules acute at both ends. Seeds are numerous (i.e. containing 8-12 seeds per plant) yellowish-brown. The leaves of Kalmegh contain maximum active principle Andrographolides, Homo-Andrographolides, Andrographersterol and Andrographone. Andrographolides the major constituent in leaves which is bitter substance. The leaves contain much more of Andrographolides then seed. The average Andrographolides content varied from 12.44 to 33.52 mg/g in dried leaves which is found maximum at 90-120 days. The whole part of the plant like leaves, stem, and roots are used in different medicine. Four lactones, viz. deoxyandrographolide, andrographolide, neo andrographolide, and deoxy didehydro andrographolide were found in Andrographis paniculata (Sangalungkarn et al., 1990). Kalmegh is used in 26 Ayurvedic formulations as evidenced from Indian Pharmacopoeia; while, in Chinese Medicine, it is an important “cold property” herb and is used to release body heat in fever and prevent the common cold. This also possesses anti diabetes, anti-jaundice, anti-inflammatory anti-ulcer genic, anti-typhoid, anti HIV, and antimalarial, antifertility, anticancer, and antiviral properties. (Joseph and Solomon, 2014). In kalmegh major economic
part of the plant is leaves. Growth regulators directly influence on the vegetative growth of the plant. Foliar application of the growth regulators directly enter the plant and it helps to increase the growth and yield of the kalmegh. So to know the potential of the plant hormones like Cycocel, GA3, and NAA the present study was undertaken with the objective to maximize growth and yield of kalmegh. It also helped to find out the different concentration of the plant hormone which increases the yield. Further, the study was taken for higher production at a lower cost.

2. MATERIALS AND METHODS
This study was conducted at A field experiment was carried out in the research farm of RAK College of Agriculture, Sehore (Madhya Pradesh) during Kharif (2015-16 and 2016-17). There were eight treatments Cycocyl @100, 150 and 200ppm, GA3 @100, 150 and 200ppm and NAA@100 and 150ppm and the water being the control. This study was done on the base of a randomized complete block design. The treatment was replicated 3 times. The plant growth regulators were sprayed in three stages viz seedling stage, vegetative stages, and reproductive stage. The local kalmegh variety seeds were sown in the main field at 30 x 15 cm spacing. The whole plot was divided into 3 blocks each representing the replication. Each block was then divided into the unit plot of 2 x 3 m size. The experiment plot fertilized with urea, single super phosphate and muriate of potash @ of NPK 75 kg, 75 kg and 50 kg ha⁻¹ respectively. All the operations are done regularly during the growing season. The growth and yield parameter observations were recorded at 90 DAS on five randomly selected plants from every treatment. The collected data include plant height, Leaf area will be determined by leaf area meter with conveyer attachment, chlorophyll content will be determined by using Minolata SPAD 502 plus Chlorophyll. The instrument measuring the relative amount of chlorophyll present in plant leaves in a unit of SPAD (Soil Plant Analysis Development). Photosynthesis rate using IRGA (Licor instruments, the USA as per method). Finally, mean data of all characters were computed for statistical analysis as per standard procedure is given by (Panse and Sukhatme 1989).

3. RESULTS AND DISCUSSIONS
3.1 Morpho-physiological Characteristics
3.1.1 Plant height (cm): The data on plant height per plant (cm) at 90 days as influenced by different plant growth hormones at harvesting was recorded during both the years and pooled data are presented in (Table -1). The impact of different concentration of plant growth hormones was significant of the crop on plant height on both the year and pooled analysis. The average plant height was higher during 2015-16 (39.57) than 2016-17 (39.41). The maximum plant height significantly during 2015-16 found was spray with GA3 150ppm (47.33) and it was at par with all other treatments due to applying with GA3 induces cell division, cell elongation, cell expansion, auxin metabolism, increase membrane permeability, photosynthesis, flowering in plants, stimulating rapid stem growth. Closely followed by spray with NAA @ 100ppm (44.68), GA3 @ 200ppm (44.63) and GA3 @ 100ppm (43.93) as compare to control (34.74) respectively. Similar results reported on the medicinal plant (Gloriosa Superba L.) by K. Kannabiran and Padmanaban (2016). During 2016-17 significantly maximum plant height was recorded spray with GA3 @100ppm (48.47) which was at par with all treatments except spray with Cycocel @ 200ppm (31.19). Closely followed by spray with NAA @ 100ppm (43.30) and GA3 @150ppm (42.32) respectively.

3.1.2 Leaf area (cm²): The data on leaf area per plant at 90 days was recorded during both the years and pooled data are presented in (Table -1). The impact of different concentration of plant growth hormones was significantly at 90 days of the crop on leaf area (cm²) per plant in both the year and pooled analysis. The average leaf area per plant was higher during 2016-17 (391.23) than 2015-16 (388.31). The maximum leaf area significantly during 2015-16 found was spray with GA3 150ppm (420.82) and it was at par with all other treatments. Closely followed by spray with GA3 @ 150ppm (415.89), GA3 @ 200ppm (414.60) and NAA @ 100ppm (410.64) as compare to control (351.78) respectively. While leaf area (cm²) was minimum (354.03) treated with Cycocel @ 200ppm (385.14). During 2016-17 significantly maximum leaf area (cm²) was recorded spray with GA3 @ 100 ppm (426.41) which was at par with all the treatments. Closely followed by spray with GA3 @ 150ppm (422.86), NAA @ 100ppm (413.30) and GA3 @ 200ppm (411.13) as compare to control (353.50) respectively. While leaf area (cm²) was minimum (358.14) treated with Cycocel @ 100ppm (358.14) due to exogenous application of GA3 evokes the intrinsic genetic potential of the plant to cause increased cell division and cell wall extensibility, thereby resulting in higher leaf area. Similar observations have been made by Srivastava and Srivastava (2007) in medicinal plant of Catharanthus roseus.

3.1.3 Chlorophyll content (SPAD): The data on Chlorophyll content was recorded during both the years and pooled data are presented in (Table -1). The impact of different concentration of plant growth hormones was nonsignificant at 90 days of the crop during both the years and pooled analysis. It was observed that there was a continuous increase in the chlorophyll content at vegetative to reproductive stages of crop growth. The average Chlorophyll content was higher during 2015-16 (51.01) than 2016-17(46.71). The maximum chlorophyll content during 2015-16 found was spray with Cycocel 100ppm (57.78) and it was at par with all other treatments. Closely followed by spray with Cycocel @ 200ppm (55.59), Cycocel @ 150ppm (54.26) and NAA @ 100ppm (53.72) respectively. While chlorophyll content was minimum (45.62) treated with NAA @ 150ppm as compare to control (41.78) respectively. The maximum chlorophyll content during 2016-17 found was spray with GA3 150ppm (49.35) and it was at par with all other treatments. Closely followed by spray with NAA @ 100ppm (49.13) and Cycocel @ 200ppm (48.93). The minimum chlorophyll was noted treated with GA3 @ 200ppm (42.68) as compared to control (43.19) respectively.

3.1.4 Photosynthesis rate (µmol CO₂ m⁻² s⁻¹): The data on photosynthesis rate was recorded during both the years and pooled data are presented in (Table -1). The impact of different concentration of plant growth hormones was significant of the crop during both the year and pooled analysis. It was observed that there was a continuous increase in the photosynthesis rate at all the stages of crop growth. Significantly higher Photosynthesis rate was observed during 2015-16 by treatment GA3 @ 100ppm (24.78) and it was at par with all other treatments. Closely followed by spray with GA3 @ 150ppm (24.21), Cycocel @ 100ppm (23.40) and NAA @ 100ppm (23.12) respectively. While photosynthesis rate was minimum (21.55) treated with Cycocel @
200ppm as compare to control (19.90) respectively. The maximum photosynthesis rate during 2016-17 found was spray with GA3 @100ppm (22.88) and it was at par with all other treatments. Closely followed by spray with GA3 @150ppm (22.24) and minimum photosynthesis rate observed treated with Cycocel @200ppm (19.19) as compared to control (18.91) respectively. The average photosynthesis rate was higher during 2015-16 (22.75) than 2016-17 (21.07).

4. CONCLUSION
From the present investigation, it can be foliar spray of growth hormones on vegetative stages and reproductive stage after seeds sown of kalmegh viz GA3 @150ppm, GA4 @ 100ppm and Cycocel @100ppm was most effective for realizing significantly maximum plant height, leaf area, chlorophyll content and photosynthesis rate during 2015-16 and spray with GA3 @100 ppm, the maximum plant height, leaf area, and photosynthesis rate was significantly differed from other treatments during 2016-17 to realize ultimately maximum profit correlated with herbage yield, alkaloid yield and seed yield of kalmegh.

5. ACKNOWLEDGMENT
We are thankful to the Department of Plant Physiology, College of Agriculture, Jabalpur (JNKVV), Department of Bioscience, RDVV, Jabalpur (Madhya Pradesh) and I ISS, Bhopal for providing lab facilities for the analysis. And with thanks for the research farm College of Agriculture, Sehore (Madhya Pradesh) for the conduct of experiments.
